## Review (and more details)

2

#### Recall: Simple Arithmetic Expressions

The set  $\ensuremath{\mathcal{T}}$  of terms is defined by the following abstract grammar:

#### Recall: Inference Rule Notation

More explicitly: The set  ${\mathcal T}$  is the  $\mathit{smallest}$  set  $\mathit{closed}$  under the following rules.

$$\label{eq:true} \begin{split} & true \in \mathcal{T} & & false \in \mathcal{T} & 0 \in \mathcal{T} \\ & \frac{t_1 \in \mathcal{T}}{succ \ t_1 \in \mathcal{T}} & \frac{t_1 \in \mathcal{T}}{pred \ t_1 \in \mathcal{T}} & \frac{t_1 \in \mathcal{T}}{iszero \ t_1 \in \mathcal{T}} \\ & \frac{t_1 \in \mathcal{T} \quad t_2 \in \mathcal{T} \quad t_3 \in \mathcal{T}}{if \ t_1 \ then \ t_2 \ else \ t_3 \in \mathcal{T}} \end{split}$$

#### **Generating Functions**

Each of these rules can be thought of as a generating function that, given some elements from  $\mathcal{T}$ , generates some other element of  $\mathcal{T}$ . Saying that  $\mathcal{T}$  is closed under these rules means that  $\mathcal{T}$  cannot be made any bigger using these generating functions — it already contains everything "justified by its members."

$$\begin{split} & \text{true} \in \mathcal{T} & \text{false} \in \mathcal{T} & 0 \in \mathcal{T} \\ & \underbrace{t_1 \in \mathcal{T}}_{\text{succ } t_1 \in \mathcal{T}} & \underbrace{t_1 \in \mathcal{T}}_{\text{pred } t_1 \in \mathcal{T}} & \underbrace{t_1 \in \mathcal{T}}_{\text{iszero } t_1 \in \mathcal{T}} \\ & \underbrace{t_1 \in \mathcal{T}}_{\text{if } t_1 \text{ then } t_2 \text{ else } t_3 \in \mathcal{T}}_{\text{3}} \end{split}$$

Let's write these generating functions explicitly.

```
\begin{array}{lll} F_1(U) &=& \{ \text{true} \} \\ F_2(U) &=& \{ \text{false} \} \\ F_3(U) &=& \{ 0 \} \\ F_4(U) &=& \{ \text{succ } \mathbf{t}_1 \mid \mathbf{t}_1 \in U \} \\ F_5(U) &=& \{ \text{pred } \mathbf{t}_1 \mid \mathbf{t}_1 \in U \} \\ F_6(U) &=& \{ \text{iszero } \mathbf{t}_1 \mid \mathbf{t}_1 \in U \} \\ F_7(U) &=& \{ \text{if } \mathbf{t}_1 \text{ then } \mathbf{t}_2 \text{ else } \mathbf{t}_3 \mid \mathbf{t}_1, \mathbf{t}_2, \mathbf{t}_3 \in U \} \end{array}
```

Each one takes a set of terms  ${\cal U}$  as input and produces a set of "terms justified by  ${\cal U}$ " as output.

If we now define a generating function for the whole set of inference rules (by combining the generating functions for the individual rules),

$$F(U) = F_1(U) \cup F_2(U) \cup F_3(U) \cup F_4(U) \cup F_5(U) \cup F_6(U) \cup F_7(U)$$

then we can restate the previous definition of the set of terms  $\ensuremath{\mathcal{T}}$  like this:

#### Definition:

- ▶ A set U is said to be "closed under F" (or "F-closed") if  $F(U) \subseteq U$ .
- ▶ The set of terms  $\mathcal T$  is the smallest F-closed set. (I.e., if  $\mathcal O$  is another set such that  $F(\mathcal O)\subseteq \mathcal O$ , then  $\mathcal T\subseteq \mathcal O$ .)

Our alternate definition of the set of terms can also be stated using the generating function F:

$$S_0 = \emptyset$$

$$S_{i+1} = F(S_i)$$

$$S = \bigcup_i S_i$$

Compare this definition of  ${\cal S}$  with the one we saw last time:

$$\begin{array}{lll} \mathcal{S}_0 & = & \emptyset \\ \mathcal{S}_{i+1} & = & \left\{ \texttt{true}, \texttt{false}, 0 \right\} \\ & \cup & \left\{ \texttt{succ } \texttt{t}_1, \texttt{pred } \texttt{t}_1, \texttt{iszero } \texttt{t}_1 \mid \texttt{t}_1 \in \mathcal{S}_i \right\} \\ & \cup & \left\{ \texttt{if } \texttt{t}_1 \texttt{ then } \texttt{t}_2 \texttt{ else } \texttt{t}_3 \mid \texttt{t}_1, \texttt{t}_2, \texttt{t}_3 \in \mathcal{S}_i \right\} \end{array}$$

$$S = \bigcup_i S_i$$

We have "pulled out" *F* and given it a name.

8

6

7

Note that our two definitions of terms characterize the same set from different directions:

- "from above," as the intersection of all F-closed sets;
- "from below," as the limit (union) of a series of sets that start from ∅ and get "closer and closer to being F-closed."

Proposition 3.2.6 in the book shows that these two definitions actually define the same set.

Warning: Hard hats on for the next slide!

9

#### Structural Induction

The principle of structural induction on terms can also be re-stated using generating functions:

```
Suppose T is the smallest F-closed set.
```

```
If, for each set U, from the assumption "P(u) holds for every u \in U" we can show "P(v) holds for any v \in F(U)," then P(t) holds for all t \in T.
```

#### Structural Induction

The principle of structural induction on terms can also be re-stated using generating functions:

```
Suppose T is the smallest F-closed set.
```

```
If, for each set U, from the assumption "P(u) holds for every u \in U" we can show "P(v) holds for any v \in F(U)," then P(t) holds for all t \in T.
```

Why?

11

11

#### Structural Induction

#### Why? Because:

- ▶ We assumed that T was the *smallest F*-closed set, i.e., that  $T \subseteq O$  for any other F-closed set O.
- ▶ But showing

```
for each set U,
given P(u) for all u \in U
we can show P(v) for all v \in F(U)
```

amounts to showing that "the set of all terms satisfying P" –call it O– is itself an F-closed set. (recall: O is F-closed if  $F(O) \subseteq O$ )

▶ Since  $T \subseteq O$ , every element of T satisfies P.

#### Structural Induction

```
If, for each term s,
given P(r) for all immediate subterms r of s
we can show P(s),
then P(t) holds for all t.
```

Recall, from the definition of  $\mathcal{S}$ , it is clear that, if a term  $\mathbf{t}$  is in  $\mathcal{S}_i$ , then all of its immediate subterms must be in  $\mathcal{S}_{i-1}$ , i.e., they must have strictly smaller depths. Therefore:

```
If, for each term s,
given P(r) for all immediate subterms r of s
we can show P(s),
then P(t) holds for all t.
```

#### Slightly more explicit proof:

- Assume that for each term s, given P(r) for all immediate subterms of s, we can show P(s).
- ► Then show, by induction on i, that P(t) holds for all terms t with depth i.
- ▶ Therefore, P(t) holds for all t.

Operational Semantics and Reasoning

15

13

14

#### Recall: Abstract Machines

An abstract machine consists of:

- ▶ a set of *states*
- ▶ a transition relation on states, written →

For the simple languages we are considering at the moment, the term being evaluated is the whole state of the abstract machine.

16

```
Recall: Syntax for Booleans

Terms and values

t ::= terms
constant true
false constant false
if t then t else t values
true true value
false false false value
```

#### Recall: Operational Semantics for Booleans

The evaluation relation  $t \longrightarrow t'$  is the smallest relation closed under the following rules:

```
\begin{array}{c} \text{if true then } t_2 \text{ else } t_3 \longrightarrow t_2 \quad \text{(E-IFTRUE)} \\ \\ \text{if false then } t_2 \text{ else } t_3 \longrightarrow t_3 \quad \text{(E-IFFALSE)} \\ \\ \\ \frac{t_1 \longrightarrow t_1'}{\text{if } t_1 \text{ then } t_2 \text{ else } t_3 \longrightarrow \text{if } t_1' \text{ then } t_2 \text{ else } t_3} \text{(E-IF)} \end{array}
```

An example

```
Let t be the term if true then (if false then false else true) else false
```

Clicker question: What is t' in  $t \longrightarrow t'$ ?

A. t' = true

 $B. \ t' = if \ true \ then \ true \ else \ false$ 

C. t'=if false then false else true

 $\ensuremath{\mathsf{D}}.$  There is no such  $\ensuremath{\mathsf{t}}'$ 

E. I don't know

URL: ttpoll.eu Session ID: cs452

18

#### **Derivations**

We can record the "justification" for a particular pair of terms that are in the evaluation relation in the form of a tree.

(on the board)

#### Terminology:

- ▶ These trees are called *derivation trees* (or just *derivations*).
- ▶ The final statement in a derivation is its conclusion.
- We say that the derivation is a witness for its conclusion (or a proof of its conclusion) it records all the reasoning steps that justify the conclusion.

20

#### Observation

Lemma: Suppose we are given a derivation tree  ${\cal D}$  witnessing the pair  $({\bf t},{\bf t}')$  in the evaluation relation. Then either

- 1. the final rule used in  $\mathcal D$  is E-IFTRUE and we have t=if true then  $t_2$  else  $t_3$  and  $t'=t_2$ , for some  $t_2$  and  $t_3$ , or
- 2. the final rule used in  $\mathcal D$  is E-IFFALSE and we have t=if false then  $t_2$  else  $t_3$  and  $t'=t_3$ , for some  $t_2$  and  $t_3$ , or
- 3. the final rule used in  $\mathcal{D}$  is E-IF and we have  $\mathsf{t} = \mathsf{if} \ \mathsf{t}_1$  then  $\mathsf{t}_2$  else  $\mathsf{t}_3$  and  $\mathsf{t}' = \mathsf{if} \ \mathsf{t}'_1$  then  $\mathsf{t}_2$  else  $\mathsf{t}_3$ , for some  $\mathsf{t}_1, \, \mathsf{t}'_1, \, \mathsf{t}_2$ , and  $\mathsf{t}_3$ ; moreover, the immediate subderivation of  $\mathcal D$  witnesses  $(\mathsf{t}_1, \, \mathsf{t}'_1) \in \longrightarrow$ .

21

#### Induction on Derivations

We can now write proofs about evaluation "by induction on derivation trees."

Given an arbitrary derivation  $\mathcal D$  with conclusion  $t \longrightarrow t'$ , we assume the desired result for its immediate sub-derivation (if any) and proceed by a case analysis (using the previous lemma) of the final evaluation rule used in constructing the derivation tree.

E.g....

#### Induction on Derivations — Example

**Theorem:** If  $t \longrightarrow t'$ , i.e., if  $(t, t') \in \longrightarrow$ , then size(t) > size(t'). **Proof:** By induction on a derivation  $\mathcal{D}$  of  $t \longrightarrow t'$ .

- 1. Suppose the final rule used in  $\mathcal{D}$  is E-IFTRUE, with t=if true then  $t_2$  else  $t_3$  and  $t'=t_2$ . Then the result is immediate from the definition of  $\emph{size}$ .
- 2. Suppose the final rule used in  $\mathcal D$  is E-IFFALSE, with  $\mathsf t=\mathsf i\mathsf f$  false then  $\mathsf t_2$  else  $\mathsf t_3$  and  $\mathsf t'=\mathsf t_3$ . Then the result is again immediate from the definition of  $\mathit{size}$ .
- 3. Suppose the final rule used in  $\mathcal{D}$  is E-IF, with  $\mathbf{t}=\mathbf{if}\ \mathbf{t}_1$  then  $\mathbf{t}_2$  else  $\mathbf{t}_3$  and  $\mathbf{t}'=\mathbf{if}\ \mathbf{t}_1'$  then  $\mathbf{t}_2$  else  $\mathbf{t}_3$ , where  $(\mathbf{t}_1,\mathbf{t}_1')\in\longrightarrow$  is witnessed by a derivation  $\mathcal{D}_1$ . By the induction hypothesis,  $\mathit{size}(\mathbf{t}_1) > \mathit{size}(\mathbf{t}_1')$ . But then, by the definition of  $\mathit{size}$ , we have  $\mathit{size}(\mathbf{t}) > \mathit{size}(\mathbf{t}')$ .

#### Normal forms

A *normal form* is a term that cannot be evaluated any further — i.e., a term t is a normal form (or "is in normal form") if there is no t' such that  $t \longrightarrow t'$ .

A normal form is a state where the abstract machine is halted — i.e., it can be regarded as a "result" of evaluation.

#### Normal forms

A *normal form* is a term that cannot be evaluated any further — i.e., a term t is a normal form (or "is in normal form") if there is no t' such that  $t \longrightarrow t'$ .

A normal form is a state where the abstract machine is halted — i.e., it can be regarded as a "result" of evaluation.

Recall that we intended the set of *values* (the boolean constants true and false) to be exactly the possible "results of evaluation." Did we get this definition right?

24

#### Values = normal forms

**Theorem:** A term  ${\bf t}$  is a value iff it is in normal form.

The  $\Longrightarrow$  direction is immediate from the definition of the evaluation relation.

#### Values = normal forms

**Theorem:** A term  ${\tt t}$  is a value iff it is in normal form.

Proof

The  $\Longrightarrow$  direction is immediate from the definition of the evaluation relation.

For the  $\longleftarrow$  direction,

25

25

#### Values = normal forms

**Theorem:** A term t is a value iff it is in normal form.

The  $\Longrightarrow$  direction is immediate from the definition of the evaluation relation.

For the  $\longleftarrow$  direction, it is convenient to prove the contrapositive: If t is not a value, then it is not a normal form.

25

26

#### Values = normal forms

**Theorem:** A term t is a value iff it is in normal form. **Proof:** 

The  $\Longrightarrow$  direction is immediate from the definition of the evaluation relation.

For the  $\longleftarrow$  direction, it is convenient to prove the contrapositive: If t is not a value, then it is not a normal form. The argument goes by induction on t.

Note, first, that t must have the form if  $t_1$  then  $t_2$  else  $t_3$ (otherwise it would be a value). If  $t_1$  is true or false, then rule  $\operatorname{E-IfTRUE}$  or  $\operatorname{E-IfFALSE}$  applies to t, and we are done. Otherwise,  $t_1$  is not a value and so, by the induction hypothesis, there is some  $t_1'$  such that  $t_1 \longrightarrow t_1'$ . But then rule E-IF yields

if  $t_1$  then  $t_2$  else  $t_3 \longrightarrow if$   $t_1'$  then  $t_2$  else  $t_3$ 

i.e., t is not in normal form.

25

 $\mathtt{t} \longrightarrow \mathtt{t}'$

#### Are all normal forms still values?

Clicker question: Propose a term that is in normal form but is *not* a value

URL: ttpoll.eu Session ID: cs452

#### Stuck terms

Formally, a stuck term is one that is a normal form but not a value.

Stuck terms model run-time errors.

28

#### Multi-step evaluation.

The multi-step evaluation relation,  $\longrightarrow$ \*, is the reflexive, transitive closure of single-step evaluation.

I.e., it is the smallest relation closed under the following rules:

$$\frac{\mathsf{t}\longrightarrow \mathsf{t}'}{\mathsf{t}\longrightarrow^*\mathsf{t}'}$$

$$\frac{t \longrightarrow^* t' \qquad t' \longrightarrow^* t''}{t \longrightarrow^* t''}$$

Termination of evaluation

**Theorem:** For every t there is some normal form t' such that

Proof:

30

31

#### Termination of evaluation

**Theorem:** For every  ${\tt t}$  there is some normal form  ${\tt t}'$  such that

▶ First, recall that single-step evaluation strictly reduces the size

if 
$$t \longrightarrow t'$$
, then  $size(t) > size(t')$ 

Now, assume (for a contradiction) that

 $t_0, t_1, t_2, t_3, t_4, \ldots$ 

is an infinite-length sequence such that

$$t_0 \longrightarrow t_1 \longrightarrow t_2 \longrightarrow t_3 \longrightarrow t_4 \longrightarrow \cdots$$

▶ Then 
$$size(t_0) > size(t_1) > size(t_2) > size(t_3) > \dots$$

▶ But such a sequence cannot exist — contradiction!

## Termination Proofs

Most termination proofs have the same basic form:

**Theorem:** The relation  $R \subseteq X \times X$  is terminating — i.e., there are no infinite sequences  $x_0$ ,  $x_1$ ,  $x_2$ , etc. such that  $(x_i, x_{i+1}) \in R$  for each i.

#### **Proof:**

- 1. Choose
  - ▶ a well-founded set (W, <) i.e., a set W with a partial order < such that there are no infinite descending chains  $w_0 > w_1 > w_2 > \dots$  in W
  - ► a function f from X to W
- 2. Show f(x) > f(y) for all  $(x, y) \in R$
- 3. Conclude that there are no infinite sequences  $x_0$ ,  $x_1$ ,  $x_2$ , etc. such that  $(x_i, x_{i+1}) \in R$  for each i, since, if there were, we could construct an infinite descending chain in W

32

34

#### Reading for next week

► Chapter 5 – Untyped Lambda Calculus (20 pages!)

The Lambda Calculus

33

### The lambda-calculus

- If our previous language of arithmetic expressions was the simplest nontrivial programming language, then the lambda-calculus is the simplest *interesting* programming language...
  - ► Turing complete
  - higher order (functions as data)
- Indeed, in the lambda-calculus, all computation happens by means of function abstraction and application.
- ► The e. coli of programming language research
- ► The foundation of many real-world programming language designs (including ML, Haskell, Scheme, Lisp, ...)

#### Intuitions

Suppose we want to describe a function that adds three to any number we pass it. We might write

```
plus3 \ x = succ \ (succ \ (succ \ x)) That is, "plus3 x is succ (succ (succ x))."
```

36

35

#### Intuitions

Suppose we want to describe a function that adds three to any number we pass it. We might write

```
plus3 \ x = succ \ (succ \ (succ \ x)) That is, "plus3 x is succ (succ (succ x))."
```

Q: What is plus3 itself?

#### Intuitions

Suppose we want to describe a function that adds three to any number we pass it. We might write

```
plus3 x = succ (succ (succ x))
```

Q: What is plus3 itself?

A: plus3 is the function that, given x, yields succ (succ (succ x).

That is, "plus3 x is succ (succ (succ x))."

36

#### Intuitions

Suppose we want to describe a function that adds three to any number we pass it. We might write

```
plus3 x = succ (succ (succ x))
That is, "plus3 x is succ (succ (succ x))."

Q: What is plus3 itself?
A: plus3 is the function that, given x, yields
succ (succ (succ x)).
```

This function exists independent of the name plus3.

 $\lambda x$ . t is written "fun  $x \to t$ " in OCaml and " $x \Rightarrow t$ " in Scala.

plus3 =  $\lambda x$ . succ (succ (succ x))

So plus3 (succ 0) is just a convenient shorthand for "the function that, given x, yields succ (succ (succ x)), applied to succ 0."

37

#### Abstractions over Functions

Consider the  $\lambda$ -abstraction

```
g = \lambda f. f (f (succ 0))
```

Note that the parameter variable  ${\tt f}$  is used in the function position in the body of  ${\tt g}$ . Terms like  ${\tt g}$  are called higher-order functions. If we apply  ${\tt g}$  to an argument like plus3, the "substitution rule" yields a nontrivial computation:

#### **Abstractions Returning Functions**

36

38

Consider the following variant of g:

```
double = \lambda f. \lambda y. f (f y)
```

l.e., double is the function that, when applied to a function f, yields a function that, when applied to an argument y, yields f (f y).

#### Example

#### The Pure Lambda-Calculus

As the preceding examples suggest, once we have  $\lambda\text{-abstraction}$  and application, we can throw away all the other language primitives and still have left a rich and powerful programming language.

In this language — the "pure lambda-calculus" — everything is a function

- ► Variables always denote functions
- ► Functions always take other functions as parameters
- ▶ The result of a function is always a function

41

## **Formalities**

Syntax

```
\begin{array}{cccc} t & ::= & & terms \\ & x & & variable \\ & \lambda x \cdot t & & abstraction \\ & t & t & application \end{array}
```

#### Term in ology:

- $\blacktriangleright$  terms in the pure  $\lambda$ -calculus are often called  $\lambda$ -terms
- $\blacktriangleright$  terms of the form  $\lambda x\,.\,\,$  t are called  $\lambda\text{-}abstractions$  or just abstractions

43

42

#### Syntactic conventions

Since  $\lambda$ -calculus provides only one-argument functions, all multi-argument functions must be written in curried style.

The following conventions make the linear forms of terms easier to read and write:

Application associates to the left

E.g., t u v means (t u) v, not t (u v)

▶ Bodies of  $\lambda$ - abstractions extend as far to the right as possible E.g.,  $\lambda x$ .  $\lambda y$ . x y means  $\lambda x$ .  $(\lambda y$ . x y), not  $\lambda x$ .  $(\lambda y$ . x) y

44

#### Scope

The  $\lambda$ -abstraction term  $\lambda x.t$  binds the variable x.

The *scope* of this binding is the *body* t.

Occurrences of x inside t are said to be *bound* by the abstraction.

Occurrences of  $\mathbf{x}$  that are *not* within the scope of an abstraction binding  $\mathbf{x}$  are said to be *free*.

Test:

 $\lambda$ x.  $\lambda$ y. x y z

45

#### Scope

The  $\lambda$ -abstraction term  $\lambda x.t$  binds the variable x.

The *scope* of this binding is the *body* t.

Occurrences of x inside t are said to be bound by the abstraction.

Occurrences of x that are *not* within the scope of an abstraction binding x are said to be *free*.

Test:

$$\lambda$$
x.  $\lambda$ y. x y z

$$\lambda x$$
. ( $\lambda y$ . z y) y

Values

 $\mathbf{v} ::= \mathbf{values}$   $\lambda \mathbf{x} . \mathbf{t} \qquad \qquad abstraction value$ 

45

#### **Operational Semantics**

Computation rule:

$$(\lambda x.t_{12}) \ v_2 \longrightarrow [x \mapsto v_2]t_{12}$$
 (E-AppAbs)

Notation:  $[x\mapsto v_2]t_{12}$  is "the term that results from substituting free occurrences of x in  $t_{12}$  with  $v_2$ ."

#### **Operational Semantics**

Computation rule:

$$(\lambda x.t_{12}) \ v_2 \longrightarrow [x \mapsto v_2]t_{12}$$
 (E-AppAbs)

Notation:  $[x \mapsto v_2]t_{12}$  is "the term that results from substituting free occurrences of x in  $t_{12}$  with  $v_2$ ."

Congruence rules:

$$\frac{\mathtt{t}_1 \longrightarrow \mathtt{t}_1'}{\mathtt{t}_1 \ \mathtt{t}_2 \longrightarrow \mathtt{t}_1' \ \mathtt{t}_2} \tag{E-App1)$$

$$\frac{\mathtt{t}_2 \longrightarrow \mathtt{t}_2'}{\mathtt{v}_1 \ \mathtt{t}_2 \longrightarrow \mathtt{v}_1 \ \mathtt{t}_2'} \tag{E-App2)$$

47

#### Terminology

A term of the form  $(\lambda x.t)$  v — that is, a  $\lambda$ -abstraction applied to a *value* — is called a *redex* (short for "reducible expression").

#### Alternative evaluation strategies

Strictly speaking, the language we have defined is called the *pure*, *call-by-value lambda-calculus*.

The evaluation strategy we have chosen —  $\it{call}$  by  $\it{value}$  —  $\it{reflects}$  standard conventions found in most mainstream languages.

Some other common ones:

- ► Call by name (cf. Haskell)
- ► Normal order (leftmost/outermost)
- ► Full (non-deterministic) beta-reduction

48

47

## Classical Lambda Calculus

#### Full beta reduction

The classical lambda calculus allows full beta reduction.

- ightharpoonup The argument of a β-reduction to be an arbitrary term, not just a value.
- Reduction may appear anywhere in a term.

51

Full beta reduction

The classical lambda calculus allows full beta reduction.

- $\blacktriangleright$  The argument of a  $\beta\text{-reduction}$  to be an arbitrary term, not just a value.
- Reduction may appear anywhere in a term.

Computation rule:

$$(\lambda x.t_{12})$$
  $t_2 \longrightarrow [x \mapsto t_2]t_{12}$  (E-AppAbs)

Full beta reduction

The classical lambda calculus allows full beta reduction.

- Reduction may appear anywhere in a term.

Computation rule:

$$(\lambda x.t_{12})$$
  $t_2 \longrightarrow [x \mapsto t_2]t_{12}$  (E-APPABS)

Congruence rules:

$$\frac{\mathtt{t}_1 \longrightarrow \mathtt{t}_1'}{\mathtt{t}_1 \ \mathtt{t}_2 \longrightarrow \mathtt{t}_1' \ \mathtt{t}_2} \tag{E-App1)$$

$$\frac{\mathtt{t}_2 \longrightarrow \mathtt{t}_2'}{\mathtt{t}_1 \ \mathtt{t}_2 \longrightarrow \mathtt{t}_1 \ \mathtt{t}_2'} \tag{E-App2)$$

$$\frac{\mathtt{t} \longrightarrow \mathtt{t}'}{\lambda \mathtt{x.t} \longrightarrow \lambda \mathtt{x.t}'} \tag{E-Abs}$$

51

51

#### Substitution revisited

Remember:  $[x \mapsto v_2]t_{12}$  is "the term that results from substituting free occurrences of x in  $t_{12}$  with  $v_2$ ."

This is trickier than it looks! For example:

$$\begin{array}{rcl} & (\lambda x. & (\lambda y. & x)) & y \\ \longrightarrow & [x \mapsto y]\lambda y. & x \\ & = & ??? \end{array}$$

Substitution revisited

Remember:  $[x\mapsto v_2]t_{12}$  is "the term that results from substituting free occurrences of x in  $t_{12}$  with  $v_2$ ."

This is trickier than it looks!

For example:

$$\begin{array}{rcl} & (\lambda x. & (\lambda y. & x)) & y \\ \longrightarrow & [x \mapsto y] \lambda y. & x \\ = & ??? \end{array}$$

Solution:

need to rename bound variables before performing the substitution.

$$(\lambda x. (\lambda y. x)) y$$

$$= (\lambda x. (\lambda z. x)) y$$

$$\longrightarrow [x \mapsto y] \lambda z. x$$

$$= \lambda z. y$$

52

#### Alpha conversion

Renaming bound variables is formalized as  $\alpha\text{--conversion}.$  Conversion rule:

$$\frac{\mathbf{y} \not\in \mathbf{fv(t)}}{\lambda \mathbf{x}. \ \mathbf{t} =_{\alpha} \lambda \mathbf{y}. [\mathbf{x} \mapsto \mathbf{y}] \mathbf{t}} \tag{a}$$

Equivalence rules:

$$\frac{\mathsf{t}_1 =_\alpha \mathsf{t}_2}{\mathsf{t}_2 =_\alpha \mathsf{t}_1} \tag{$\alpha$-Symm}$$

$$\frac{\mathtt{t}_1 =_\alpha \mathtt{t}_2 \qquad \mathtt{t}_2 =_\alpha \mathtt{t}_3}{\mathtt{t}_1 =_\alpha \mathtt{t}_3} \qquad \qquad (\alpha\text{-Trans})$$

Congruence rules: the usual ones.

Confluence

Full  $\beta$ -reduction makes it possible to have different reduction paths.

Q: Can a term evaluate to more than one normal form?

53

52

#### Confluence

Full  $\beta$ -reduction makes it possible to have different reduction paths.

Q: Can a term evaluate to more than one normal form?

The answer is no; this is a consequence of the following

#### **Theorem** [Church-Rosser]

Let  $\mathbf{t}$ ,  $\mathbf{t}_1$ ,  $\mathbf{t}_2$  be terms such that  $\mathbf{t} \longrightarrow^* \mathbf{t}_1$  and  $\mathbf{t} \longrightarrow^* \mathbf{t}_2$ . Then there exists a term  $\mathbf{t}_3$  such that  $\mathbf{t}_1 \longrightarrow^* \mathbf{t}_3$  and  $\mathbf{t}_2 \longrightarrow^* \mathbf{t}_3$ .

# Programming in the Lambda-Calculus

54

#### Multiple arguments

Consider the function  ${\tt double}$ , which returns a function as an argument.

```
double = \lambda f. \lambda y. f (f y)
```

This idiom — a  $\lambda$ -abstraction that does nothing but immediately yield another abstraction — is very common in the  $\lambda$ -calculus.

In general,  $\lambda x$ .  $\lambda y$ . t is a function that, given a value v for x, yields a function that, given a value u for y, yields t with v in place of x and u in place of y.

That is,  $\lambda x$ .  $\lambda y$ . t is a two-argument function.

(Recall the discussion of currying in OCaml.)

#### The "Church Booleans"

56

57

#### Functions on Booleans

```
not = \lambdab. b fls tru
```

That is, not is a function that, given a boolean value v, returns fls if v is tru and tru if v is fls.

#### Functions on Booleans

```
and = \lambdab. \lambdac. b c fls
```

That is, and is a function that, given two boolean values v and w, returns w if v is tru and fls if v is fls

Thus and v w yields tru if both v and w are tru and fls if either v or w is fls.

58

#### **Pairs**

```
pair = \lambda f. \lambda s. \lambda b. b f s
fst = \lambda p. p tru
snd = \lambda p. p fls
```

That is, pair v w is a function that, when applied to a boolean value b, applies b to v and w.

By the definition of booleans, this application yields v if b is tru and w if b is fls, so the first and second projection functions fst and snd can be implemented simply by supplying the appropriate boolean.

#### Example

60

61

#### Church numerals

Idea: represent the number  $\it n$  by a function that "repeats some action  $\it n$  times."

```
\begin{array}{l} c_0 \; = \; \lambda s. \;\; \lambda z. \;\; z \\ c_1 \; = \; \lambda s. \;\; \lambda z. \;\; s \;\; z \\ c_2 \; = \; \lambda s. \;\; \lambda z. \;\; s \;\; (s \; z) \\ c_3 \; = \; \lambda s. \;\; \lambda z. \;\; s \;\; (s \; (s \; z)) \end{array}
```

That is, each number n is represented by a term  $c_n$  that takes two arguments, s and z (for "successor" and "zero"), and applies s, n times, to z.

#### Functions on Church Numerals

What about predecessor?

63

#### Predecessor

```
zz = pair c_0 c_0
```

ss =  $\lambda$ p. pair (snd p) (scc (snd p))

prd =  $\lambda$ m. fst (m ss zz)

Recursion in the Lambda-Calculus

65

#### Recursion and divergence

Recursion and divergence are intertwined, so we need to consider divergent terms.

 $= (\lambda x. x x) (\lambda x. x x)$ 

Note that  ${\tt omega}$  evaluates in one step to itself! So evaluation of omega never reaches a normal form: it diverges.

66

### Recursion and divergence

Recursion and divergence are intertwined, so we need to consider divergent terms.

 $(\lambda x. x x) (\lambda x. x x)$ 

Note that omega evaluates in one step to itself! So evaluation of omega never reaches a normal form: it diverges.

Being able to write a divergent computation does not seem very useful in itself. However, there are variants of omega that are very useful...

Recall: Normal forms

- A normal form is a term that cannot take an evaluation step.
- A stuck term is a normal form that is not a value.

Does every term evaluate to a normal form?

No, omega is not in normal form.

But are there any stuck terms in the pure  $\lambda$ -calculus?

#### Recall: Normal forms

- A normal form is a term that cannot take an evaluation step.
- A stuck term is a normal form that is not a value.

Does every term evaluate to a normal form?

No, omega is not in normal form.

67

67

#### Towards recursion: Iterated application

Suppose  ${\tt f}$  is some  $\lambda\text{-abstraction,}$  and consider the following variant of <code>omega:</code>

```
Y_f = (\lambda x. f (x x)) (\lambda x. f (x x))
```

68

#### Towards recursion: Iterated application

Suppose  ${\bf f}$  is some  $\lambda\text{-abstraction,}$  and consider the following variant of omega:

```
Y_f = (\lambda x. f (x x)) (\lambda x. f (x x))
```

Now the "pattern of divergence" becomes more interesting:

```
\begin{array}{c} Y_f \\ = \\ \underline{(\lambda x. \ f \ (x \ x)) \ (\lambda x. \ f \ (x \ x))} \\ \longrightarrow \\ f \ (\underline{(\lambda x. \ f \ (x \ x)) \ (\lambda x. \ f \ (x \ x))}) \\ \longrightarrow \\ f \ (f \ (\underline{(\lambda x. \ f \ (x \ x)) \ (\lambda x. \ f \ (x \ x))}))) \\ \longrightarrow \\ f \ (f \ (\underline{(\lambda x. \ f \ (x \ x)) \ (\lambda x. \ f \ (x \ x))}))) \\ \longrightarrow \\ \cdots \end{array}
```

68

 $Y_f$  is still not very useful, since (like omega), all it does is diverge. Is there any way we could "slow it down"?

#### Delaying divergence

```
poisonpill = \lambda y. omega
```

Note that poisonpill is a value — it will only diverge when we actually apply it to an argument. This means that we can safely pass it as an argument to other functions, return it as a result from functions, etc.

```
\begin{array}{c} (\lambda p. \  \, \text{fst (pair p fls) tru) poisonpill} \\ \longrightarrow \\ \text{fst (pair poisonpill fls) tru} \\ \longrightarrow^* \\ & \underline{\text{poisonpill tru}} \\ \longrightarrow \\ & \text{omega} \\ \longrightarrow \\ \cdots \end{array}
```

70

#### A delayed variant of omega

Here is a variant of omega in which the delay and divergence are a bit more tightly intertwined:

$$\begin{array}{rcl} & \text{omegav} & = \\ \lambda \mathbf{y}. & (\lambda \mathbf{x}. & (\lambda \mathbf{y}. & \mathbf{x} & \mathbf{y})) & (\lambda \mathbf{x}. & (\lambda \mathbf{y}. & \mathbf{x} & \mathbf{y})) & \mathbf{y} \end{array}$$

Note that omegav is a normal form. However, if we apply it to any argument v, it diverges:

71

73

#### Another delayed variant

Suppose f is a function. Define

```
z_f = \lambda y. (\lambda x. f (\lambda y. x x y)) (\lambda x. f (\lambda y. x x y)) y
```

This term combines the "added  $\mathbf{f}$ " from  $\mathbf{Y}_f$  with the "delayed divergence" of omegav.

72

If we now apply  $\mathbf{z}_f$  to an argument  $\mathbf{v},$  something interesting happens:

```
\begin{array}{c} \mathbf{z_f} \ \mathbf{v} \\ = \\ \\ \underline{(\lambda \mathbf{y}.\ (\lambda \mathbf{x}.\ \mathbf{f}\ (\lambda \mathbf{y}.\ \mathbf{x}\ \mathbf{x}\ \mathbf{y}))\ (\lambda \mathbf{x}.\ \mathbf{f}\ (\lambda \mathbf{y}.\ \mathbf{x}\ \mathbf{x}\ \mathbf{y}))\ \mathbf{y}\ \mathbf{v}} \\ - \\ \underline{(\lambda \mathbf{x}.\ \mathbf{f}\ (\lambda \mathbf{y}.\ \mathbf{x}\ \mathbf{x}\ \mathbf{y}))\ (\lambda \mathbf{x}.\ \mathbf{f}\ (\lambda \mathbf{y}.\ \mathbf{x}\ \mathbf{x}\ \mathbf{y}))}\ \mathbf{v} \\ - \\ \mathbf{f}\ (\lambda \mathbf{y}.\ (\lambda \mathbf{x}.\ \mathbf{f}\ (\lambda \mathbf{y}.\ \mathbf{x}\ \mathbf{x}\ \mathbf{y}))\ (\lambda \mathbf{x}.\ \mathbf{f}\ (\lambda \mathbf{y}.\ \mathbf{x}\ \mathbf{x}\ \mathbf{y}))\ \mathbf{y})\ \mathbf{v} \\ = \\ \mathbf{f}\ \mathbf{z_f}\ \mathbf{v} \end{array}
```

Since  $\mathbf{z}_f$  and  $\mathbf{v}$  are both values, the next computation step will be the reduction of  $\mathbf{f}$   $\mathbf{z}_f$  — that is, before we "diverge,"  $\mathbf{f}$  gets to do some computation.

Now we are getting somewhere.

Recursion

Let

```
 \begin{array}{lll} f & = & \lambda f ct \, , & \\ & & \lambda n \, , & \\ & & \text{if n=0 then 1} \\ & & \text{else n * (fct (pred n))} \end{array}
```

f looks just like the ordinary factorial function, except that, in place of a recursive call in the last lime, it calls the function fct, which is passed as a parameter.

N.b.: for brevity, this example uses "real" numbers and booleans, infix syntax, etc. It can easily be translated into the pure lambda-calculus (using Church numerals, etc.).

We can use  $z_f$  to "tie the knot" in the definition of  ${\tt f}$  and obtain a real recursive factorial function:

```
\begin{array}{c} z_f \ 3 \\ \longrightarrow^* \\ f \ z_f \ 3 \\ = \\ (\lambda f c t. \ \lambda n. \ \ldots) \ z_f \ 3 \\ \longrightarrow \longrightarrow \\ \text{if 3=0 then 1 else } 3 * (z_f \ (pred \ 3)) \\ \longrightarrow^* \\ 3 * (z_f \ (pred \ 3))) \\ \longrightarrow \\ 3 * (z_f \ 2) \\ \longrightarrow^* \\ 3 * (f \ z_f \ 2) \\ \ldots \end{array}
```

75

```
A Generic z
```

If we define

```
i.e., z = \\ \lambda f. \ \lambda y. \ (\lambda x. \ f \ (\lambda y. \ x \ x \ y)) \ (\lambda x. \ f \ (\lambda y. \ x \ x \ y)) \ y
```

 $z = \lambda f. z_f$ 

then we can obtain the behavior of  $z_f$  for any  ${\tt f}$  we like, simply by applying  ${\tt z}$  to  ${\tt f}.$ 

```
{	t z} {	t f} \longrightarrow {	t z}_f
```

76

```
For example:
```

```
fact = z ( \lambdafct. 
 \lambdan. 
 if n=0 then 1 
 else n * (fct (pred n)) )
```

**Technical Note** 

The term  ${\bf z}$  here is essentially the same as the  ${\tt fix}$  discussed the book.

```
z = \lambda f. \lambda y. (\lambda x. f (\lambda y. x x y)) (\lambda x. f (\lambda y. x x y)) y
fix = \lambda f. (\lambda x. f (\lambda y. x x y)) (\lambda x. f (\lambda y. x x y))
```

z is hopefully slightly easier to understand, since it has the property that z f v  $\longrightarrow$  f (z f) v, which fix does not (quite) share.

77
